

FLEXIBLE FABRIC FROM FIBROUS WEB AND DISCONTINUOUS DOMAIN  
MATRIX

ABSTRACT OF THE DISCLOSURE

- A composite having a plurality of filaments arranged in a fibrous web that is held  
5 together in a unitary structure by a domain matrix. The domain matrix comprises a  
plurality of matrix islands that individually connect, or bond, at least two filaments, to  
thereby hold the filaments in a unitary structure. Portions of the filament lengths  
within the unitary structure are free of matrix islands, causing the domain matrix to be  
discontinuous. The composite possesses a greater flexibility than coated structures.  
10 The composite may be formed into cross-ply structures. A method of making the  
composite also is disclosed.
